If you have a growing season of at least 90-100 days and plenty of space, you can be the proud owner of several short handled (14”- 20”) dipper gourds by fall.

The vines will quickly cover a trellis, hide a chain-link fence, wrap around trees, and then keep growing! Despite the vine's need for vast amount of space, it's a fascinating plant to grow that adults and kids love. The resulting gourds can be made into birdhouses, feeders, rattles, ladies (dippers) – use your imagination!!

The vine requires a long hot growing season of 90 - 100 days. Since gourds demand a long growing season, they can be started indoors 4 weeks prior to planting outdoors. If you start them indoors, gourd seeds should be planted in individual containers, such as peat pots, since their roots will not like being disturbed during transplanting.

If you started your plants indoors, you need to start "conditioning" the plants to the great outdoors a few days before transplanting. Outdoors generally has lower humidity, less frequent rainfall and higher light levels, and if you plant your babies out directly, they may wilt. Instead, start taking them outside in the shade for a few hours a day—then letting them have some direct sunlight for a couple hours a day, shade the rest. Let them wilt just a tiny, tiny bit while they're outside. Give them at least 3-4 days of this sort of "abuse" before you plant them out. This is called "hardening off" and it generally results in plants that just keep right on growing without breaking stride. Once the danger of frost is past and your plants are hardened off, plant the peat pots in tilled soil that has a LOT of compost added – they grow BEST ON NEW ground (no previous crops).

For straight-necked gourds, plant on a fence line, planting about 6 seeds together in a ‘hill’ (I make a trench about 12” long and space them in there), ½” deep, and allowing 30’ of fence (15’ in each direction) per hill. When they have 2 or 3 of their first real leaves, thin to leave the strongest 3 vines per hill. You may also plant the vines where they can climb onto a STRONG trellis or even a tree. You can grow them on the ground, as well – this will result in a crook-necked dipper. When growing on the ground, after the gourd begins to form I usually place a piece of Styrofoam under it to keep it from staying too wet and rotting. Gourds like a soil pH around 6-6.5, slightly acidic and are best grown on NEW GROUND or soil with LOTS of added compost/organic material. If you plant during dry months, you will need to water the vines until they are established or there is heavy rain at least weekly. Once you have vines growing, do not fertilize them again or you'll have beautiful leaves and few gourds. The only pest I have had a problem with on gourds is leaf-miner. Watch for their tell-tale “tunnels” on your leaves and treat with appropriate insecticide.
Once the vine is about 10 to 15 feet long, pinch off the tip of the main runner so that the plant will send out side branches. It's on these side branches that the female flowers (and gourds) grow. This is very important, otherwise, you may have many flowers but few gourds.

There are male flowers that need to pollinate the female ones. Female flowers have a little bulge behind the flower that looks a bit like a little birdhouse gourd. Male flowers only have a stem. If you have plenty of bees and insects, they will do all of the work naturally for you. Or at night when the flowers open up, take a bit of the male pollen and shake it onto the female flowers. One vine may produce up to 12 gourds. If a gourd begins growing low on the fence and touches the ground, you may want to put a small piece of Styrofoam under it to keep the moisture in the ground from rotting the gourd.

The vines will love many long drinks of water throughout the summer. But when autumn approaches, do not give them any supplemental waterings. Let the vines wither and die as winter approaches.

Leave the gourds on the vine until a light frost or the stems turn brown. If you need to pick a gourd before the frost, the gourd should be very firm to the touch. Cut the gourd with an inch or more of stem. Wash the gourds in soapy water. Household bleach may be added to the water if desired, and may help delay mold formation. After the first frost, cut the gourds from the vines and put them in a dry warm place on a screen or hang them. It is important that air can circulate all about them, drying them. If a gourd becomes soft and begins to rot or becomes shriveled, throw it away (save the seeds!!). However, a bit of mold on the gourds is fine and normal. It may take 6 months to dry large gourds. They will be ready when they are very light in weight, and you can hear the seeds inside rattle when you shake the birdhouse gourd.

**Drying**

Dry the gourd fruits naturally by placing in an area with good air circulation. Bringing the gourds indoors may help them dry faster, but gourds can be dried outdoors even in cold areas, however repeated freezing and thawing will affect the viability of seeds. When the seeds rattle, the gourd is dry and ready for crafting. How long it takes a gourd to dry depends on the drying environment -- the warmer and the better the circulation, the faster the water will evaporate from the gourd. Most moderate-sized hardshell gourds will be dry by Christmas. Larger or particularly thick-shelled gourds may not dry for several more months. Light may help to retard formation of mold, but the mold on the outside of gourds is a natural part of the drying process; as long as the gourd remains firm to the touch, do not discard it. Turning the gourds and wiping off the mold on a weekly basis may help the gourds dry sooner.

Once the gourds are dried, they can be crafted in a number of different ways. You can do just about anything to them that you can do with wood – cutting, carving, painting, staining – let your imagination run wild!
Saving Seeds

Seeds from your gourds, whether the gourds have been dried or not, can be saved for planting next year. If I harvest seeds from a green gourd, I rinse them off (there is a ‘slime’ on them in the green gourds) and place them in a warm, dry area to dry completely. I store all my seeds in breathable containers (not plastic bags).

Make note, however: Growing many types of gourds or squash in close proximity to each other WILL affect your seeds by creating cross-pollinated gourds. The gourds themselves will be fine, but the seeds may well produce something that does not resemble your original. In reality, there is no 100% guaranteed distance to avoid cross-pollination because bees and moths can fly long distances, but I keep my gourds 200 – 300 feet apart to considerably reduce the chances of cross pollination.
